# SCREEN-PRINTED CARBON ELECTRODE MODIFIED GNPs/ZnO FOR ELECTROCHEMICAL SENSING

## Abstract

Screen-printed carbon electrodes (SPCEs) modified with graphene nanoplatelets (GNPs) and zinc oxide (ZnO) are widely used in electrochemical sensors due to their enhanced electrochemical properties and biocompatibility. Screen-printed carbon electrodes modified with Graphene nanoplatelets (GNPs) /Zinc oxide (ZnO) nanocomposite are described. In this study, GNPs/ZnO nanocomposite was synthesized, characterized, and applied to an electrochemical sensor. The formation of GNPs/ZnO nanocomposite was characterized by UV-Vis spectroscopy and scanning electron microscopy. Moreover, SPCEs/GNPs/ZnO nanocomposite were characterized using cyclic voltammetry to optimize the concentration of the nanocomposite. Then, the analytical performance of the sensor was studied by measuring methylparaben as an organic compound using differential pulse voltammetry (DPV) as a preliminary study before using it for biosensing. This result showed a significant improvement in electrocatalytic activity and reproducibility. The ratio of GNPs/ZnO nanocomposite concentrations was found that 1 mg/mL GNPs/ZnO nanocomposite has the highest current response. Moreover, the study of the detection methyl paraben is highly sensitive with limit of detection (LOD) around  $9.7 \mu\text{M}$ , selective, and good reproducibility of SPCE-GNPs/ZnO. Hence, the proposed sensor of SPCE-GNPs/ZnO displayed good performance, sensitivity, and reproducibility.

**Keywords:** SPCE, GNPs/ZnO nanocomposite, electrochemical

## I. INTRODUCTION

Screen printing technology is an electrode printing technology that uses materials such as carbon, metals, plastic, and ceramics [1]. Screen printing can be fabricated in large quantities based on carbon electrodes that are reproducible, low-cost, and disposable. Recently screen-printed carbon electrodes have been used in various electrochemical fields. The most applications are in chemical and biochemical sensors, energy conversion and storage, and microelectronics [2][3].

SPCE performance can be improved by chemical modification—the purpose of modification is to increase the electron transfer rate and electrode selectivity. The modifier selection significantly affects the performance of the electrode. One of the modifiers that can be used to improve the electron transfer rate on SPCE is graphene/ZnO nanoparticles [4][5]. Graphene nanoplatelets (GNPs) are stacks of multiple graphene layers with some lateral dimensions in the nanoscale. Adding GNPs to SPCEs enhances the electrode's electrocatalytic properties, increases the surface area, and improves electron transfer kinetics.

GNPs can also immobilize biomolecules like enzymes or antibodies, essential for biosensing applications. In the application, graphene tends to re-stacking due to strong van der Waals and  $\pi$ -bond interaction. Re-stacking can cause graphene to lose most of its surface area. It is necessary to incorporate metal or metal oxide into graphene layers to prevent re-stacking [6].

In nanotechnology, metal oxide nanostructures are the greatest nanostructures among other nanomaterials because they have a large surface area, low toxicity, are environmentally friendly, have good chemical stability, and are biocompatible. ZnO is a metal oxide with semiconductor properties, a wide bandgap (3.37 eV), and excitation binding energy (60 meV) [7]. In addition, ZnO is non-toxic, with high surface area and electron transfer. ZnO is a transducer material that converts biochemical reactions into measurable electrical signals. It can enhance the specificity and sensitivity of the biosensor due to its unique electrical properties and ability to bind with specific biomolecules. Therefore, ZnO is widely used in various fields, such as electronics, optoelectronics, and biosensors [7][8].

Figure 1. The schematic of electrochemical detection of organic compounds such as methylparaben.

1 Figure 1 exhibited the electrochemical reaction  
 2 involving methylparaben on the GNPs/ZnO electrode. I  
 3 the schematic described, the carbon/ZnO electrode is the  
 4 working electrode in this setup. Methylparaben, a  
 5 organic compound, can undergo oxidation or reduction  
 6 reactions at the electrode surface. During the oxidation  
 7 process, the carbon/ZnO electrode can oxidize  
 8 methylparaben molecules, releasing electrons. This  
 9 process is facilitated by the ZnO component of the  
 10 electrode, which acts as a catalyst for the oxidation  
 11 reaction. On the other hand, during the reduction process,  
 12 the carbon/ZnO electrode can accept electrons from the  
 13 environment and reduce methylparaben molecules. This  
 14 reduction reaction can also occur in the presence of an  
 15 external power source, such as a battery.

16 This study modified SPCE by GNPs/ZnO  
 17 nanocomposites, which were used for applications in  
 18 electrochemical sensors. The modification aims to  
 19 improve the electrocatalytic properties of the electrodes,  
 20 producing an electrochemical sensor that is more  
 21 sensitive to detecting organic compounds. The  
 22 preliminary study of the developed sensor was used to  
 23 directly detect methylparaben, one of the most prevalent  
 24 compounds in pharmaceutical, food, and cosmetic  
 25 products.

## 26 II. METHOD

### 27 A. Materials & Apparatus

28 Graphene nanoplatelets, zinc acetate dihydrate  
 29 ( $\text{Zn}(\text{CH}_3\text{COO})_2 \cdot 2\text{H}_2\text{O}$ ) (99.5-101.0%), Kalium chloride  
 30 (KCl), Potassium ferricyanide ( $\text{K}_3\text{FeCN}_6$ ), Potassium  
 31 ferrocyanide ( $\text{K}_4\text{FeCN}_6$ ), phosphate buffer were  
 32 purchased from Merck, chitosan with medium molar  
 33 weight was purchased from Sigma-Aldrich (Germany).  
 34 Silver paste, Ag/AgCl paste, dielectric paste, and carbon  
 35 paste for fabricated SPCE were purchased from  
 36 SunChemical® and metil paraben from Brataco  
 37 (Indonesia).

38 The electrochemical measurements were performed  
 39 with PGSTAT302 potentiostat-galvanostat using a three  
 40 electrode configuration. Screen-printed carbon  
 41 electrodes were fabricated with a screen-printing  
 42 machine. The morphology of ZnO nanoparticles and  
 43 GNPs/ZnO nanocomposite was observed by a scanning  
 44 electron microscope (SEM) (JEOL JSM IT300) with an  
 45 accelerating voltage of 20 kV. The absorption was  
 46 obtained by UV-Vis spectroscopy (Agilent  
 47 Technologies-8453).

### 48 B. Fabrication of SPCE

49 Screen-printed carbon electrodes were fabricated  
 50 with three different pastes for each electrode. The  
 51 schematic structure of SPCE is shown in Figure 2. The  
 52 electrodes were deposited onto a polytetrafluoroethylene  
 53 (PTFE) substrate. (a) Electrode pad layers were deposited  
 54 using Ag paste at 140 for 30 minutes; this layer serves as  
 55 the conducting path of the electrode to contact with  
 56 reference, auxiliary, and working electrodes, (b) carbon  
 57 paste was deposited as working and auxiliary electrode,  
 58 (c) Ag/AgCl layer as reference electrode, and (d)  
 59 encapsulation layer was deposited to prevent cross-talk  
 60 among electrodes. Each electrode was cured in an oven

at a suitable temperature based on mesh size, modified  
 inks, and screen printing parameters, including pressure  
 and ink distribution. Strip's general dimensions: 3.4 x 1.0  
 x 0.05 cm. Working (4 mm diameter) and counter/  
 auxiliary electrodes made of carbon.

Figure 2. The schematic structure of fabricated SPCE consists of (a) an electrode pad, (b) a working and auxiliary electrode, (c) a reference electrode, and (d) an encapsulation layer.

The fabricated SPCE was characterized by cyclic  
 voltammetry at 0.01M  $\text{K}_3\text{FeCN}_6/\text{K}_4\text{FeCN}_6$  solution, and  
 the result was compared by SPCE commercial (Metrohm  
 DropSens).

### 71 C. Synthesis of GNPs/ZnO nanocomposite

GNPs/ZnO nanocomposite was synthesized using  
 commercial GNPs, and ZnO nanoparticles were  
 synthesized based on the following procedure in previous  
 work [9]. GNPs and ZnO nanoparticles were mixed in  
 ethanol and stirred using a magnetic stirrer for four hours.  
 The solution was centrifuged, and the precipitation was  
 washed using ultra-pure water and then dried in an oven  
 at 80° C. The morphology of nanocomposite products  
 was characterized using SEM.

### 72 D. Optimization of nanocomposite concentrations and analytical performance of sensor

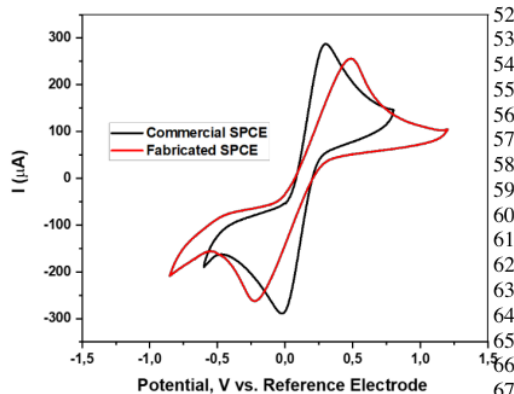

The optimization of nanocomposite concentration was  
 carried out at concentrations of 0.5, 1.0, and 1.5 mg/mL  
 of nanocomposite. The nanocomposite powder was  
 dispersed in ethanol and sonicated for 30 minutes.  
 Subsequently, 2.5 – 5.0  $\mu\text{L}$  solution was drop cast onto  
 the surface working electrode, and then the electrode was  
 dried in oven for 30 minutes. Each electrode was  
 analyzed by cyclic voltammetry at a potential range of -  
 1 to 1.2 V; scan rate 100  $\text{mV} \cdot \text{s}^{-1}$  with  $\text{K}_3\text{FeCN}_6/\text{K}_4\text{FeCN}_6$   
 and 0.1 M KCl solution. The performance of electrodes  
 was analyzed by differential pulse voltammetry (DPV) at  
 a potential range of 0.1 to 1.2 V, with the scan rate of 100  
 mV/s in methyl paraben and phosphate buffer solution at  
 pH 7.

## 73 III. RESULTS AND DISCUSSION

### 74 A. Voltammetry characterization of SPCE

The ferri/ferrocyanide redox couple was used for  
 comparing the voltammetric behavior of fabricated SPCE  
 and SPCE commercials. Potassium hexacyanoferrate (II)  
 and potassium hexacyanoferrate (III) are chosen as

1 models because they can characterize electrochemical  
2 systems in aqueous and organic solutions [10]. As show  
3 in Figure 3, typical voltammetric profiles result from the  
4 following electrochemical process:

6  
7 Figure 3 Voltammogram fabricated SPCE vs commercial SPCE

8 The peak separations of the anodic and cathodic  
9 peak current of fabricated spce are 0.2758 V, and the  
10 commercial spce is 0.2807 V, respectively. The substrate,  
11 paste, dimensions, and fabrication process can cause a  
12 difference in peak separation. The difference in the paste  
13 may include information regarding particle size,  
14 components, etc. At the same time, the fabrication  
15 process consists of the curing temperature. In this study,  
16 the low-curing temperature must be used with PTFE  
17 substrate; meanwhile, the high-curing temperature can be  
18 used with ceramics alumina substrate as in commercial  
19 SPCE. The difference can affect a significant limiting  
20 factor in charge transfer [10][11][12]. The cathodic and  
21 anodic current ratios for fabricated SPCE and  
22 commercial SPCE are close to 1. It shows reversible  
23 properties of  $\text{K}_3\text{FeCN}_6/\text{K}_4\text{FeCN}_6$ . Hence, the fabricated  
24 spce can be used for further experiments.

## 26 B. Characterization of GNPs/ZnO nanocomposite 27 and SPCE-GNPs/ZnO

28 Dispersion of ZnO nanoparticles was characterized  
29 using UV-Vis spectrophotometry. By measuring the  
30 absorbance at different wavelengths, the UV-Vis  
31 spectrophotometer can provide information about the  
32 dispersion of ZnO nanoparticles. The absorbance  
33 spectrum can reveal the presence of any aggregation or  
34 agglomeration of nanoparticles, as well as the size and  
35 shape of the nanoparticles. The UV-Vis spectra (Figure  
36 4a) showed a sharp peak with high intensity at  
37 wavelength 366.50 nm, indicating that the ZnO  
38 nanoparticle on the nanometer scale and particle size  
39 distribution is narrow, the SEM image (Figure 4b) shows  
40 that the morphology of ZnO N.P.s are spherical and  
41 confirm particle distribution is narrow size range from  
42 33-70 nm [13][14][15]. After the hybridization of GNPs  
43 and ZnO, the nanocomposite of GNPs/ZnO was  
44 characterized by scanning electron microscopy as shown  
45 in Figure 4c. The hybridization of GNPs and ZnO offers

the opportunity to combine the unique properties of both  
materials, resulting in enhanced or synergistic effects.

There are some key aspects of the hybridization of  
GNPs and ZnO NPs, such as enhanced electrical  
properties. GNPs possess excellent electrical  
conductivity due to their graphene structure, while ZnO  
is a semiconductor material. By combining the two, the  
electrical conductivity of the composite can be improved,  
making it suitable for applications in electronics, sensors,  
or energy devices. GNPs have a large surface area,  
providing a high contact area for ZnO nanoparticles. This  
increased surface area allows for more interactions  
between the two materials, leading to improved  
properties such as enhanced catalytic activity or  
increased surface reactivity. The combination of GNPs  
and ZnO can result in synergistic effects, where the  
properties of the composite are greater than the sum of its  
components. This can include improved conductivity,  
enhanced optical properties, or increased stability,  
depending on the specific application and composition of  
the hybrid material.

7  
 1 Figure 4 (a) UV-Vis spectra and (b) SEM image of ZnO nanoparticle,  
 2 (c) SEM image of GNP/ZnO nanocomposite.  
 3  
 4 18  
 4 Figure 5 shows the SEM images of GNP/ZnO. The  
 5 flake layer is GNPs, and ZnO nanoparticle was  
 6 embedded onto the GNPs surface sheet. The ZnO  
 7 nanoparticles are supported by the GNPs, increasing the  
 8 surface area and resulting in improved properties. The  
 9 ZnO NPs reduce the van Der Waals force among  
 10 graphene sheets; thus, the graphene did not undergo  
 11 aggregation [16][17]. By utilizing GNPs as a support, the  
 12 surface area available for ZnO nanoparticles is increased.  
 13 This increased surface area allows more ZnO  
 14 nanoparticles to be present, leading to a higher  
 15 concentration of active sites. As a result, the properties of  
 16 the composite material, such as catalytic activity,  
 17 electrical conductivity, or sensing capabilities, can be  
 18 improved [18][19].

 21  
 22

22 C. Analytical performance of electrodes and  
 23 optimization concentrations of nanocomposite

24 The behavior of bare SPCE and modified SPCE was  
 25 investigated using cyclic voltammetry in a potential  
 26 range from -1.2 V to 1.2 V at a scan rate of 100 mV/s in  
 27 0.01 M phosphate buffer containing 0.1 M KCl (pH 7.0).  
 28 [17] has been chosen as a convenient and effective  
 29 technique to investigate the surface characteristics of  
 30 electrodes [20].  
 31

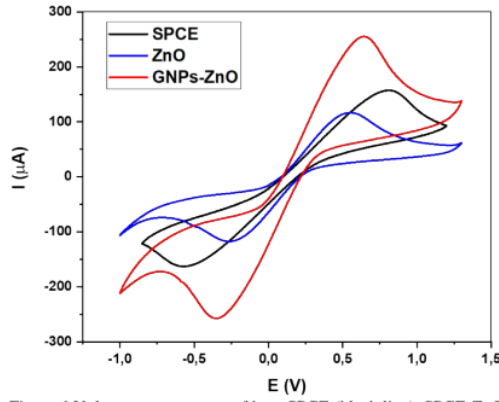

Figure 6 Voltammogram curve of bare SPCE (black line), SPCE-ZnO (blue line), and SPCE-GNP/ZnO (red line).

As shown in Figure 6, the current response of  $K_3[Fe(CN)_6]$  at bare SPCE is higher than SPCE-ZnO. Factors influencing the response, since ZnO NPs tended to agglomerate when the modified electrode was dried after drop casting the ZnO NPs on the surface electrode. Subsequently, reducing the surface area of the electrode then reducing the electrochemical response [21][22]. The increasing current response is observed after modification of SPCE with GNP/ZnO nanocomposite. This suggests that the presence of ZnO nanoparticles introduces electrochemical activity or redox processes, potentially due to the inherent properties of ZnO, such as its semiconductor behavior or catalytic activity.

On the other hand, when GNP/ZnO composites are formed on the SPCE surface (SPCE-GNP/ZnO, represented by the red line), the voltammogram curve exhibits further changes compared to the SPCE-ZnO curve. The presence of graphene nanoplatelets (GNPs) in the composite can enhance electrical conductivity and increase surface area, leading to improved electrochemical performance. The red line indicates that the SPCE-GNP/ZnO composite may show a higher current response or additional redox peaks than the bare SPCE (red line) and SPCE-ZnO (blue line), indicating the synergistic effects of the hybrid material. In addition, the increasing current is also associated with increasing electrical conductivity and the surface-to-volume ratio of the electrode, which suggests that GNP/ZnO nanocomposite is an effective modification in electrodes [20][23]. The difference between current response and peak-to-peak separation can be seen in Table 1.

TABLE 1  
 THE ELECTROCHEMICAL RESPONSE OF BARE ELECTRODES AND MODIFIED ELECTRODES

Electrodes	$E_{pa}$	$E_{pc}$	$I_{pa}$	$I_{pc}$
Bare SPCE	0.757	0.527	100.97	65.74
SPCE-ZnO	0.615	0.303	213.1	173.54
SPCE-GNP/ZnO	0.520	0.225	102.26	86.89

The optimization concentrations of the nanocomposite were investigated by cyclic voltammetry in 0.01 M  $K_3FeCN_6/K_4FeCN_6$  solution containing 0.1 M KCl. The amounts of nanocomposite on the surface electrode could affect the current response of electrodes due to the

1 catalytic properties of GNPs/ZnO nanocomposite  
 2 enhancing the electron transfer [24][25]. This can be  
 3 controlled by using different concentrations of  
 4 GNPs/ZnO (0.5, 1, and 1.5 mg/mL) using the same  
 5 volume (2.5  $\mu$ L) on the SPCE surface.  
 6

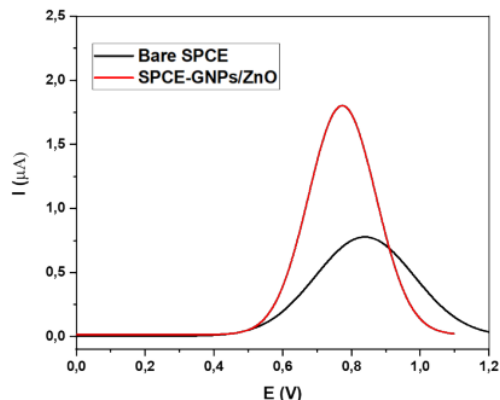

7  
 8 Figure 7 The current response of K3/K4 in different concentrations of  
 9 GNPs/ZnO nanocomposite.

10  
 11 As shown in Figure 7, the peak current for 1 mg/mL was  
 12 obtained to be the highest. The further concentrations of  
 13 nanocomposite in lower and higher than 1 mg/mL caused  
 14 a gradual decrease in peak current. The lower  
 15 concentrations are possibly related to not being  
 16 distributed well. In comparison, the higher  
 17 concentrations are connected to an increase in the  
 18 thickness of the nanocomposite layer due to decreasing  
 19 the surface-ratio-to-volume of the surface working  
 20 electrode [25][26]. Hence, GNPs/ZnO nanocomposite  
 21 with a 1 mg/mL concentration was selected as the  
 22 optimum concentration for the modified electrode.  
 23

#### 24 D. The use of GNPs/ZnO nanocomposite-based 25 sensor for methylparaben detection.

26 The study's main concern is the application of nano  
 27 structured electrodes for electrochemical sensors. One of  
 28 the applications GNPs/ZnO nanocomposite-based  
 29 sensors is the detection of organic compounds  
 30 specifically methylparaben. The study of the detection of  
 31 methylparaben was investigated by the Differential pulse  
 32 voltammetry method at a potential range of 0.1 to 1.2  
 33 with a scan rate of 100 mV/s in 1 mM methylparaben  
 34 DPV has been chosen as a voltammetry technique  
 35 because the DPV method gives a sensitivity response  
 36 than CV [24][25].  
 37

38  
 39 Figure 8. DPV voltammogram of 1 mM methyl paraben at bare spce  
 40 (black line) and SPCE-GNPs/ZnO (red line).  
 41  
 42

43  
 44 Figure 8 indicates that the shifting peak current in  
 45 Differential Pulse Voltammetry (DPV) between a bare  
 46 SPCE and an SPCE-GNPs/ZnO electrode can be  
 47 influenced by several factors, such as, enhanced  
 48 electrocatalytic activity: The incorporation of graphene  
 49 nanoplatelets (GNPs) and zinc oxide (ZnO) on the SPCE  
 50 surface can enhance its electrocatalytic activity. This  
 51 increased activity can lead to higher peak currents for the  
 52 analyte species than the bare SPCE electrode. The  
 53 shifting peak current observed between the two  
 54 electrodes can be attributed to the difference in their  
 55 catalytic properties. Improved electron transfer kinetics:  
 56 GNPs and ZnO on the SPCE electrode can facilitate  
 57 faster electron transfer between the electrode surface and  
 58 the analyte species. This improved electron transfer  
 59 kinetics can result in higher peak currents and a shifting  
 60 peak current between the bare SPCE and SPCE-  
 61 GNP/ZnO electrodes. Surface area effect: Incorporating  
 62 GNPs and ZnO on the SPCE electrode surface increases  
 63 its effective surface area. This increased surface area  
 64 provides more active sites for the analyte species to  
 65 interact with, leading to higher peak currents. The  
 66 shifting peak current observed between the two  
 67 electrodes can be due to the difference in their surface  
 68 areas and the corresponding availability of active sites.  
 69 Synergistic effect: Combining GNPs and ZnO on the  
 70 SPCE electrode can create a synergistic effect that  
 71 enhances the electrochemical response. This synergistic  
 72 effect can lead to higher peak currents and a shifting  
 73 peak current between the bare SPCE and SPCE-GNP/ZnO  
 74 electrodes [24].

75 As shown in Figure 8, SPCE-GNPs/ZnO have a  
 76 higher current response and lower potential oxidation  
 77 than bare SPCE. This suggests better sensitivity and  
 selectivity due to the synergistic effect of GNPs and ZnO  
 that enhances electrocatalytic electron transfer [25].

Figure 9. (a) DPV voltammogram of 1 mM methyl paraben. (b) Current peak response of 1 mM methyl paraben at SPCE-GNPs/ZnO.

The reproducibility of SPCE-GNPs/ZnO was measured using three different electrodes in 1 mM methylparaben. As shown in Figure 9a and b, The RSD for SPCE-GNPs/ZnO was obtained to be 4.54 %, and the peak of potential anodic was stable at an average of 0.7754 V. The modified electrode shows acceptable reproducibility, as the RSD value is less than 10 % [27]. This means the measurements obtained using different SPCE-GNPs/ZnO electrodes in 1 mM methylparaben are relatively consistent and reliable. These results demonstrate that the SPCE-GNPs/ZnO electrode is reproducible and can directly detect organic compounds (especially methylparaben) without a mediator.

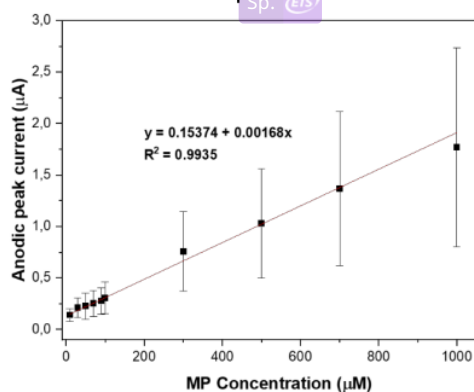

Figure 10. Anodic peak current vs. concentration of methylparaben ranging from 100 – 1000  $\mu$ M in PBS pH 7 at SPCE-GNPs/ZnO.

The sensitivity and linearity performance of SPCE-GNPs/ZnO were evaluated by differential pulse voltammetry at a different concentration under optimization conditions. This study reveals the developed sensor's working linear range and detection limit. The calibration curve of methylparaben was obtained by plotting current values against the concentration. As shown in Figure 10, the peak oxidation current of methylparaben increases with increasing concentration, and the peak current of methylparaben oxidation has a good linear relationship from 10 – 1000  $\mu$ M. Above 1000  $\mu$ M, the peak current becomes constant or saturated, which indicates the saturation of the recognition site in the sensing layer.

The limit of detection was calculated according to linear regression  $y = 0.15374 + 0.00168x$  ( $R^2 = 0.993$ ) from the calibration curve and the equations of  $LOD = 3 \delta b/b$  with  $\delta b$  being the standard deviation, and  $S$  is the slope of linear calibration plot. Hence, the calculated limit of detection is 9.7  $\mu$ M.

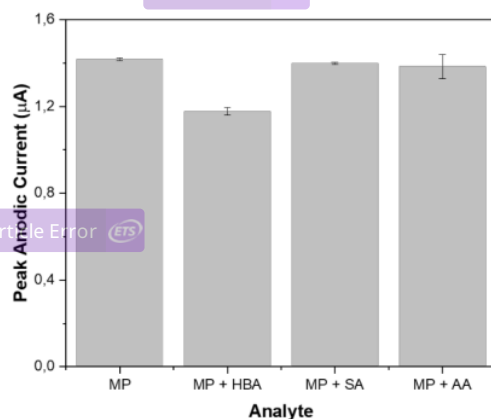

Figure 11. The peak current of selectivity test on SPCE-GNPs/ZnO.

The selectivity of the study was assessed using the oxidative current response of methylparaben (MP) in the presence of potential interfering substances. A few select interfering compounds were chosen, including 4-hydroxy benzoic acid (HBA) due to its similar structure to MP. Additionally, salicylic acid (SA) and ascorbic acid (AA) were included as they are commonly used in healthcare products.

An interference study was conducted on solutions containing binary mixtures of the target analyte methylparaben (MP) and various interference substances at a 1:1 concentration ratio (mol/mol). As shown in Figure 11, no significant interference peaks were observed. Furthermore, salicylic acid and ascorbic acid did not exhibit any interference, and the oxidation current peaks were very close to the oxidation current peaks of MP. Therefore, the interference substances did not affect the measurement of MP. This result suggests that the sensor demonstrated specific recognition and selectivity for MP. However, a slight decrease in peak current response was observed in hydroquinone B (HBA) in

1 solution due to HBA's smaller size than MP. Moreover,  
2 the molecular structures of MP and HBA are similar, thus  
3 creating strong competition between the two molecules  
4 to occupy cavities in the sensitive layer matrix. This  
5 result implies that the imprinted cavities were formed  
6 specifically to selectively detect MP.

#### 7 IV. CONCLUSION

8 In conclusion, this investigation presents a study that  
9 highlights the synthesis, characterization, and utilization  
10 of a nanocomposite consisting of Graphene nanoplatelets  
11 (GNPs) and Zinc oxide (ZnO) to modify screen-printed  
12 carbon electrodes (SPCEs) in the realm of  
13 electrochemical sensors. The GNPs/ZnO nanocomposite  
14 formation was effectively characterized by means of UV-  
15 Vis spectroscopy and scanning electron microscopy.  
16 Cyclic voltammetry was employed to optimize the  
17 concentration of the nanocomposite on SPCEs,  
18 ultimately revealing that a concentration of 1 mg/mL of  
19 GNPs/ZnO nanocomposite showcased the highest  
20 current response. The sensor's performance was  
21 evaluated by detecting methylparaben, an organic  
22 compound, utilizing differential pulse voltammetry  
23 (DPV). The findings indicate a significant enhancement  
24 in electrocatalytic activity and reproducibility, coupled  
25 with a heightened sensitivity, selectivity, and a low limit  
26 of detection (LOD) of approximately 9.7  $\mu\text{M}$  for  
27 detecting methylparaben. Overall, the proposed SPCE  
28 GNPs/ZnO sensor demonstrates exceptional  
29 performance, sensitivity, and reproducibility, laying the  
30 groundwork for potential applications in the field of  
31 biosensing. This research contributes to the advancement  
32 of electrochemical sensors by employing modified  
33 screen-printed carbon electrodes adorned with  
34 GNPs/ZnO nanocomposite, which provides heightened  
35 electrochemical properties and biocompatibility for  
36 precise and dependable detection of organic compounds.
